Constraint Satisfaction Problem

Basic terms about CSP:

Node Consistency

Arc Consistency Algorithm(AC-3)

Path consistency

Backtracking

Improving backtracking efficiency

Forward checking

Arc consistency

Structure

Tree-structure CSPs

Algorithm for tree-structured CSPs

Nearly tree-structured CSPs

Local Search for CSPs

Min-Conflict Algorithms

1. Chapter 1:Constraint Satisfaction Problem

1.1 Constraint Satisfaction Problem

Constraint satisfaction problems(CSP) are mathematical problems defined as a set of objects whose state must satisfy a number of constraints or limitations. One example of a CSP is the game “Sudoku”

1.2 Basic terms about CSP:

- an assignment is to assign values to some or all variables
- an assignment that does not violate any constraints is called a consistent assignment. With values from domain D_i
- A complete assignment is one in which each variable is assigned
- a partial assignment is one that assigns value to some of the variables

Constraint graph

Binary CSP: each constraint relates at most two variables, e.g: WASA constraint graph: nodes are variables(e.g. region WA), arcs show constraints(e.g. WASA)

Varieties of Variables

Discrete variables

- Finite Domains
- boolean CSPs, include: boolean satisfiability(NP - complete)
- Sudoku
- Infinite Domains(Integers, Strings, etc.)
- job scheduling, variables are start/end days for each job, need a constraint language, e.g.
 $StartJob_1 + 5 \leq StarJob_3$

Continuous variables

- start /end times for Hubble Telescope observations
- Unary constraints involve a single variable
 - $SA \neq Green$

- binary constraints involve pairs of variables
 - $SA \neq WA$
- Higher-order constraints involve 3 or more variables
 - cryptarithmic column constraints
- Preferences(soft) constraints
 - red is better than green
 - CSPs with preference are often with optimization search algorithms constraints optimization problems

1.2.1 Node Consistency

If a node is node-consistent if all the value's domain satisfy the variable's unary constraints.

Example:

$D = \text{Red, Green, Blue}$

Variable X

X dislikes green, then X starts with $D = \text{Red, Green, Blue}$, and becomes node consistent after eliminating Green. X is node consistent with the reduced domain, $D = \text{Red, Blue}$.

Arc Consistency

X_i is arc-consistent with respect to another variables X_j if for every value in X_i 's current domain D_i there is one value in X_j 's domain D_j that satisfies the binary constraint on the arc (X_i, X_j)

Example:

Given two variables X_i, X_j with values in $0, 1, 2, \dots, 9$ and constraints $(0, 0), (1, 1), (2, 4), (3, 9)$.

To make X_i arc-consistent with respect to X_j , we reduce X_i 's domain to $0, 1, 2, 3$.

To make X_j arc-consistent with respect to X_i , we reduce X_j 's domain to $0, 1, 4, 9$.

1.3 Arc Consistency Algorithm(AC-3)

function AC-3(*csp*) **returns** false if an inconsistency is found and true otherwise

inputs: *csp*, a binary CSP with components (X, D, C)

local variables: *queue*, a queue of arcs, initially all the arcs in *csp*

```

while queue is not empty do
  ( $X_i, X_j$ )  $\leftarrow$  REMOVE-FIRST(queue)
  if REVISE(csp,  $X_i, X_j$ ) then
    if size of  $D_i = 0$  then return false
    for each  $X_k$  in  $X_i$ .NEIGHBORS -  $\{X_j\}$  do
      add ( $X_k, X_i$ ) to queue
return true

```

function REVISE(*csp*, X_i, X_j) **returns** true iff we revise the domain of X_i

revised \leftarrow false

for each x **in** D_i **do**

if no value y in D_j allows (x, y) to satisfy the constraint between X_i and X_j **then**

 delete x from D_i

revised \leftarrow true

return revised

1. initially let a queue contain all arcs
2. remove an arc (X_i, X_j) from the queue and make the variable X_i arc-consistent to X_j
 - (a) IF X_i domain D_i is unchanged, then check the next arc in the queue
 - (b) IF X_i 's domain D_i is revised(smaller), then add all arcs (X_k, X_i) in the queue
 - (c) If X_i 's domain D_i is empty, then CSP no solution
3. Keep checking all arcs in the queue until the queue is empty

1.4 Path consistency

A two variable set X_i, X_j is path consistency with respect to a third variable X_m if for every assignment $X_i = a, X_j = b$ consistent with the constraints on X_i, X_j , where is an assignment to X_m , that satisfies the constraints on X_i, X_m and X_m, X_j

Example:

Can we color the Australia map with two colors?

Make the set WA, SA path consistent with respect to NT?

Assignments: WA = blue, SA = red or WA =blue,SA=red

But no assignment exists for NT

Constraint propagation

- constraint propagation is a specific type of inference
 - use the constraints to reduce the number of legal values for a variable, which in turn can reduce the legal values for another variable, and so on
- node consistency
- arc consistency
- path consistency
- k-consistency: k variables involved
- Global consistency

Limits

- Indeed AC-3 works for the easiest Sudoku puzzles
- slightly harder ones can be solved by PC-2, but at a greater computational cost: there are 255,960 different path constraints to consider in a Sudoku puzzle
- To solve the hardest puzzles and to make efficient progress, we will have to be more clever

1.5 Backtracking

1. Select an unassigned value
2. assign values
3. Depth-first search
4. If an inconsistency is detected, then BACKTRACK returns failure, causing the previous call to try another value

Backtracking search is a depth-first search for CSPs

- choose values for one variable at a time
- backtrack when a variables has no legal left to assign

Backtracking search is the basic uninformed algorithm for CSP. Can solve n-queens for $n \approx 25$.

```

function BACKTRACKING-SEARCH(csp) returns a solution, or failure
  return BACKTRACK({ }, csp)

function BACKTRACK(assignment, csp) returns a solution, or failure
  if assignment is complete then return assignment
  var ← SELECT-UNASSIGNED-VARIABLE(csp)
  for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
    if value is consistent with assignment then
      add { var = value } to assignment
      inferences ← INFERENCE(csp, var, value)
      if inferences ≠ failure then
        add inferences to assignment
        result ← BACKTRACK(assignment, csp)
        if result ≠ failure then
          return result
      remove { var = value } and inferences from assignment
  return failure

```

1.5.1 Improving backtracking efficiency

General-purpose methods can give huge gains in speed:

1. which variable should be assigned next?
2. in what order should values be tried?
3. can we detect inevitable failure early?
4. Can we take advantage of problem structure?

Minimum remaining values

Minimum remaining values (MRV): choose the variable with the fewest legal values.

Degree heuristic

- Tie-breaker among MRV variables
- Degree heuristic: choose the variable with the most constraints on remaining variables

Least constraining value

Given a variable, choose the least constraining value: the one that rules out the fewest values in the remaining variables.

these heuristics makes 1000 queens feasible.

Combining

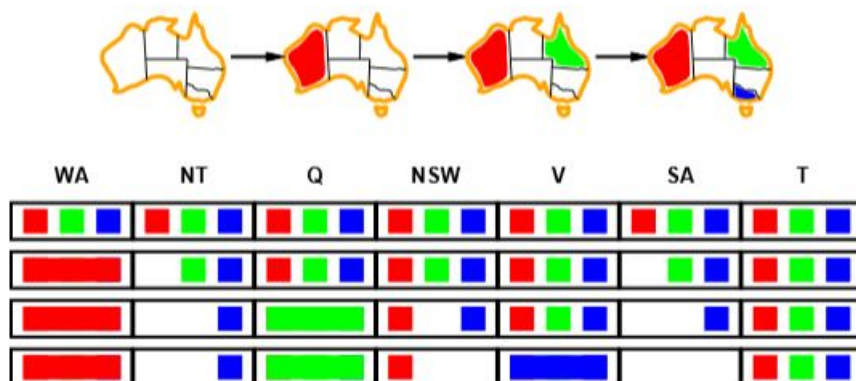

1.5.2 Forward checking

Idea: Keep track of remaining legal values for unassigned variables.
Terminates search when any variable has no legal values.

Constraint propagation

Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

NT and SA cannot both be blue!

Constraint propagation repeatedly enforces constraints locally.

1.5.3 Arc consistency

Simplest form of propagation makes each arc consistent.

$X \rightarrow Y$ is consistent if for every value x of X there is some allowed y

If X loses a value, neighbours need to be rechecked.

Arc consistency detects failure earlier than *forward checking*. Can be run as a predecessor or after each assignment.

1.6 Structure

Tasmania and mainland Australia are independent subsections which can be identified as connected components of constraint graph.

- Suppose each subproblem has a c variable out of n total
- Worst-case solution cost is $n/c * d^c$ linear in n
- E.g. $n = 80, d = 2, c = 20$
 - $2^{80} = 4$ billion years at 10 million nodes/sec
 - $2 * 2^{20} = 0.4$ seconds at 10 million nodes/sec

1.6.1 Tree-structure CSPs

- Theorem: if the constraint graph has no loops, the CSP can be solved in $O(nd^2)$ time
- Compare to general CSPs, where worst-case time is $O(d^n)$
- This property also applies to logical and probabilistic reasoning: an important example of the relation between syntactic restrictions and the complexity of reasoning

1.6.2 Algorithm for tree-structured CSPs

1. Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering
2. For j from n down to 2, apply *RemoveInconsistent*(*Parent*(X_j), x_j)
3. For j from 1 to n , assign X_j consistently with *Parent*(X_j)

1.6.3 Nearly tree-structured CSPs

- Conditioning: instantiate a variable, prune its neighbours domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size $c \Rightarrow \text{runtime } O(d^c * (n - c)d^2)$, very fast for small c

- Choose a subset S from $VARIABLE[csp]$ such that the constraint graph becomes a tree after removal of S
- For each possible assignment to the variables in S satisfies all constraint on S
 - remove from the domains of the remaining variables any values that are inconsistent with the assignment of S
 - If the remaining CSP has solution, then return it together the assignment to S

1.7 Local Search for CSPs

- Local search, e.g. hill-climbing, simulated annealing for CSP
 - typically start with a "complete" state, i.e. all variables assigned to values, but may violated constraints
 - then search changes the value of one variable at each time for violated constraints
- Variable selection: randomly select any conflicted variable
- Value selection by min-conflicts heuristics:
 - choose value that violates the fewest constraints i.e. hillclimb with $h(n)$ = total number of violated constraints

1.7.1 Min-Conflict Algorithms

function MIN-CONFLICTS(*csp*, *max_steps*) **returns** a solution or failure

inputs: *csp*, a constraint satisfaction problem

max_steps, the number of steps allowed before giving up

current \leftarrow an initial complete assignment for *csp*

for *i* = 1 to *max_steps* **do**

if *current* is a solution for *csp* **then return** *current*

var \leftarrow a randomly chosen conflicted variable from *csp*.VARIABLES

value \leftarrow the value *v* for *var* that minimizes CONFLICTS(*var*, *v*, *current*, *csp*)

 set *var* = *value* in *current*

return failure

- Given random initial state, can solve *n*-queens in almost constant time for arbitrary *n* with high probability (e.g. $n = 10000000$)
- The same to be true for any randomly-generated CSP *except* in a narrow range of the ratio $R = \frac{\text{number of constraints}}{\text{number of variables}}$
